

Swing Point

Indicators & Analysis / Levels & Patterns | intermediate | 5 min read | DeepCharts Help Center | July 20, 2026

Every trader marks swing highs and swing lows — the local peaks and troughs where price turned. The Swing Point indicator does it for you: it identifies significant swings using a customizable lookback and draws horizontal lines at those price levels, so your support and resistance map updates itself as the market prints new structure.

Because the definition of a swing is fully parameterized, you control how selective the indicator is — from every minor wiggle to only the major turning points.

What it is

The Swing Point indicator answers the question "where did price most recently turn, and at what levels?" A **swing high** is a bar whose high is higher than the highs of a set number of bars on both sides; a **swing low** is the mirror image with lows. When a bar qualifies, the indicator draws a horizontal line at that level, with labels, so the level remains visible as price trades away from it.

Swing highs mark potential resistance and reversal zones; swing lows mark potential support. Together they outline the market structure most price-action methods are built on.

When to use it

- To keep an always-current map of support and resistance levels without drawing lines manually.
- To read market structure: a sequence of higher swing highs and higher swing lows defines an uptrend, and a break of that sequence is an early trend-change warning.
- To find stop placement and target references — swings are where resting orders naturally cluster.
- To feed other analysis: divergence and confluence work is usually anchored at swing points (see Divergence Detector and Confluence Identifier).

Quick start

1. Open a chart and click the bar-chart icon in the top-left corner to open the **Indicators** panel.
2. Click **Indicators** to open the full **Indicator List**.
3. Search for "Swing Point" and click + to add it.
4. Click the gear icon next to the indicator to open its settings. Start with the defaults (**Left Bars 2, Right Bars 2**) and increase both if the chart shows more swing lines than you can use.
5. Set distinct **High Color** and **Low Color** values so resistance and support levels are distinguishable at a glance.

How to read it

- **Swing high lines** are levels where sellers previously overwhelmed buyers — watch for rejection (resistance holding) or acceptance (breakout) when price returns to them.
- **Swing low lines** are the support-side mirror.
- **Selectivity is your dial.** With small **Left Bars / Right Bars** values you see many minor swings — useful for scalping structure. Larger values keep only the more significant turns that define the higher-timeframe picture.

- **Confirmation lags by design.** A swing cannot be confirmed until the required number of right-side bars has printed, so a new swing line appears only after that many bars have closed beyond the extreme. Higher **Right Bars** values mean the indicator waits longer for confirmation — fewer false swings, later signals.

Settings reference

General Parameters

Setting	What it does
Left Bars	Number of bars to the left of the candidate bar that must have lower highs (for a swing high) or higher lows (for a swing low). Increasing this value makes the indicator more selective, identifying only more significant swings. Default: 2.
Right Bars	Number of bars to the right that must show lower highs or higher lows before the swing is validated. Higher values mean the indicator waits longer for confirmation. Default: 2.
Filter Swing	When activated, applies additional filtering that removes minor swings which do not meet quality thresholds, reducing noise.

Plot Settings

Setting	What it does
Line Width	Thickness of the horizontal swing lines. Default: 2.
Line Style	Style of the swing lines. Default: Dash — dashed lines keep swing levels visually distinct from other chart elements.
High Color	Color of swing high lines (resistance/reversal zones).
Low Color	Color of swing low lines (support/reversal zones).
Text Tick Offset	Distance, in ticks, between a swing line and its text label. Default: 1.
Text Size	Size of the swing labels. Default: 11.00.
High Text Color	Text color for swing high labels.
Low Text Color	Text color for swing low labels.

Tips and common mistakes

- **Don't treat a fresh swing as tradeable the bar it forms.** The line appears **Right Bars** bars after the actual extreme; by then price has already moved away. Use swings as levels for the next visit, not as entry signals at confirmation.
- **Match selectivity to timeframe.** Left/Right of 2 on a 1-minute chart produces a dense web of lines; either raise the values or enable **Filter Swing** before concluding the indicator is "too noisy".
- **Symmetric values are a starting point, not a rule.** A larger **Right Bars** than **Left Bars** demands more proof that the turn held, which suits swing traders; scalpers often prefer the opposite trade-off.
- **Read swings as structure, not standalone signals.** A broken swing low in an uptrend matters because of what it says about the higher-low sequence — combine the lines with a trend read rather than fading every level.
