

Absolute Levels

Indicators & Analysis / Levels & Patterns | intermediate | 4 min read | DeepCharts Help Center | July 20, 2026

The Absolute Levels indicator draws horizontal lines at price values you type in yourself. It is a technical analysis tool for marking key support and resistance levels on an asset's price chart — but unlike automated level indicators, you choose the exact prices, and the indicator keeps them plotted with your chosen formatting.

That makes it the right tool for levels that come from your own analysis or from outside the chart entirely: a settlement price, a round number, a level from a higher-timeframe study, or a price flagged in a trading plan.

What it is

Absolute Levels is a manual levels indicator. You enter up to two fixed price values — **First Value** and **Second Value** — and the indicator plots each as a horizontal line with independently configurable color, style and thickness. It answers the question "where are my pre-decided prices relative to the market right now?"

When to use it

- You have exact prices from your trading plan (entries, invalidation levels, targets) and want them fixed on the chart.
- You track prices that no automatic indicator produces — round numbers, settlement, a news-event level.
- You want levels that never move: unlike calculated levels, absolute levels stay exactly where you put them until you change them.
- You want a pair of reference lines with distinct formatting — for example, a green target line and a red risk line.

Quick start

1. Open the **Indicator List** on your chart.
2. Find **Absolute Levels** and click **+** to add it.
3. Click the **Settings** icon next to the indicator.
4. Enter the price for your first level in **First Value** and the price for your second level in **Second Value**.
5. Give the two lines contrasting formatting — for example, a solid line for the more important level and a dashed line for the secondary one — using each line's **Color**, **Style** and **Thickness** settings.
6. Apply and confirm both lines sit exactly at the prices you entered.

How to read it

Absolute Levels adds no calculation of its own — the interpretation is whatever meaning your prices carry:

- **Price approaching a level** is your cue to pay attention: watch how the market behaves into your pre-marked price rather than deciding in the moment.

- **A clean rejection at a level** validates the analysis that produced the price; a decisive close beyond it invalidates that idea and turns the line into a potential retest reference from the other side.
- **Two levels form a bracket.** With one value above and one below price, you have a simple range map: outside the bracket the market is doing something your plan should account for.

Settings reference

Grouped as in the settings dialog.

Parameters

Setting	What it does
First Value	Price of the first absolute level displayed on your chart.
Second Value	Price of the second absolute level displayed on your chart.

First Line

Setting	What it does
First Line Color	Color of the first plotted line.
First Line Style	Visual style of the first plotted line.
First Line Thickness	Width of the first plotted line.

Second Line

Setting	What it does
Second Line Color	Color of the second plotted line.
Second Line Style	Visual style of the second plotted line.
Second Line Thickness	Width of the second plotted line.

Tips and common mistakes

- **Update the values when your plan changes.** Absolute levels do not roll over or recalculate; a stale line from last week’s plan is worse than no line. Review the values as part of your session prep.
- **Use it alongside — not instead of — calculated levels.** Automated tools such as Important Levels and Pivot Points cover the standard reference prices; reserve Absolute Levels for the handful of prices only you are tracking.
- **Differentiate the two lines visually.** If both lines share a color and style, you lose the information of which level is which; encode meaning in the formatting.
- **Prefer this over a drawn line when precision matters.** Typing the exact value into **First Value** avoids the small placement errors of dragging a drawing by hand — see Drawing Tools and Annotations for when a freehand line is the better fit.
