

# Deep Profile (Volume / Delta Profile)

Indicators & Analysis / Deep Indicators | intermediate | 7 min read | DeepCharts Help Center | July 20, 2026

Deep Profile is the volume-by-price indicator in DeepCharts: it plots trading activity by price rather than by time, drawing a histogram of how much volume (or delta) traded at each price level. The various profile buttons on the chart all enable this same indicator — each button is a different preset configuration of Deep Profile.

Where a candle chart answers "what happened when," a profile answers "where did the business get done" — which prices the market accepted and which it rejected.

## What it is

Deep Profile builds histograms of executed volume per price level over a period you choose — the latest session, one profile per day, a single composite over all loaded data, exactly what is visible on screen, or any custom area you select. The histogram can show total volume, ask/bid split, delta, or delta and volume together.

## When to use it

- You want to locate the prices where the most business was done — support/resistance grounded in actual traded volume, not lines drawn by eye.
- You trade session levels: prior-day POC, high-volume nodes and low-volume voids.
- You want to compare buying vs selling pressure by price (Ask/Bid or Delta profiles).
- You need a profile of one specific area — a consolidation, a swing, a news spike — via the Visible or Custom periods.

## Quick start

1. Open a chart and add **Deep Profile** from the chart's **Indicators** button (or click one of the profile buttons — they are presets of this indicator).
2. Open the settings and set **VBP Type** to **Volume Profile**.
3. Set **VBP Period** to **Multiple** with **Length Type** = Days and a **Length Value** of 1 for one profile per day.
4. Apply — each day now shows its own volume histogram. Try the live profile below: hover the rows and drag the Value Area % to see how the POC and the VAH/VAL boundaries respond.

## Recommended starter configuration

Suggestions, not defaults:

| Area            | Suggested start                                                                                                                        |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------|
| VBP Type        | <b>Volume Profile</b> first; add a <b>Delta Profile</b> later to see directional pressure                                              |
| VBP Period      | <b>Multiple</b> , Length Type = Days, Length Value = 1                                                                                 |
| Input Data      | <b>Volume</b> ; try <b>Aggregate</b> when you care about reconstructed large orders (see Different Types of Input Data for Indicators) |
| Tick grouping   | <b>Automatic</b> ; switch to Manual with Manual Tick = 1 if your levels shift when zooming                                             |
| POC             | Enabled, with <b>Show Line</b> on so the level extends visibly                                                                         |
| Peak and Valley | Enable once you are comfortable — start with higher sensitivity for fewer, more significant nodes                                      |

## How to read it

- **The histogram:** longer bars mark prices where more volume traded — areas of acceptance where the market spent time doing business. Short bars mark rejection — prices the market moved through quickly.
- **POC (Point of Control):** the level where the highest trading volume occurred within the profile. It acts as the gravitational center of the period and is a widely watched reference.
- **Developing POC:** with Line Type set to **Developing**, you see the historical migration trail of the POC as the session built — useful for judging whether value was moving up or down.
- **Peaks and valleys:** peaks are high-volume nodes (typically shown in red) where price tends to slow; valleys are low-volume zones (typically green) that price tends to traverse quickly.
- **Delta profiles:** a positive delta at a level means aggressive buyers outnumbered aggressive sellers there; sustained negative delta into a low-volume area can flag initiative selling.

For the underlying concepts — value area, HVN/LVN, and how profiles frame a trading day — see Understanding Volume Profile: POC, Value Area, HVN/LVN. If you want only the key levels (POC, value area, VWAP) without the histogram, use Deep Profile Values.

## Settings reference

Grouped as in the indicator dialog.

### General settings

| Setting                           | What it does                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>VBP Type</b>                   | Profile variety: <b>Volume Profile</b> (total traded volume at each price level), <b>Ask/Bid Volume Profile</b> (buying and selling pressure separated), <b>Delta Profile</b> (difference between aggressive buyers and sellers per level), <b>Delta and Total Volume</b> (delta on the left, volume on the right)                                                        |
| <b>VBP Period</b>                 | Data scope: <b>Latest</b> (most recent profile only), <b>Multiple</b> (separate profiles per selected time period), <b>Composite</b> (a single profile over all loaded data), <b>Visible</b> (profile of exactly the data on screen — recalculates as you scroll and zoom), <b>Custom</b> (profile over any hand-selected chart area, with shortcuts on the left toolbar) |
| <b>Length Type / Length Value</b> | Profile frequency — e.g. Length Type = Days with Length Value = 2 creates a new profile every two days. Minute, daily, weekly and monthly units are supported                                                                                                                                                                                                             |

### Data settings

| Setting                   | What it does                                                                                                                                                                                                                                                         |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Input Data</b>         | Calculation basis: <b>Volume</b> , <b>Order</b> , <b>Aggregate</b> , or <b>Number of Trades</b> (individual trade counts instead of total volume). Different input types produce visibly different profile shapes — see Different Types of Input Data for Indicators |
| <b>Min and Max Filter</b> | Size thresholds — e.g. a minimum filter of 20 excludes orders smaller than 20                                                                                                                                                                                        |
| <b>Tick Grouping</b>      | Bar height: <b>Automatic</b> (calculated by DeepCharts) or <b>Manual</b> (e.g. Manual Tick = 5 groups five ticks per bar)                                                                                                                                            |

**Note:** With Automatic tick grouping, bar heights — and therefore the exact POC/level prices — can shift as you zoom the price scale. To freeze the levels, set grouping to Manual with Manual Tick = 1.

### Filter / Split Time

| Setting                                  | What it does                                                                                            |
|------------------------------------------|---------------------------------------------------------------------------------------------------------|
| <b>Filter Mode: Splitted</b>             | Draws multiple profiles within the same trading day — for example separate ETH and RTH session profiles |
| <b>Filter Mode: Triple + Custom Time</b> | Three separate profiles per day over custom time ranges                                                 |

**Warning:** Custom filter times use the time zone of the exchange for the instrument you are trading — always, regardless of your local clock. Entering local times here silently builds profiles over the wrong hours.

### POC of Profile

| Setting                              | What it does                                                                                       |
|--------------------------------------|----------------------------------------------------------------------------------------------------|
| <b>Enable</b>                        | Toggles POC display — the level with the highest traded volume                                     |
| <b>Highlight Enable / Color</b>      | Highlights the POC bar with a custom color                                                         |
| <b>Show Line / Line Type</b>         | Draws a horizontal POC line; <b>Developing</b> shows the historical POC locations as they migrated |
| <b>Extended Line Till End Window</b> | Extends the POC line across the visible chart                                                      |
| <b>Line Color / Width</b>            | Styling of the POC line                                                                            |

### Peak and Valley

| Setting                | What it does                                                                 |
|------------------------|------------------------------------------------------------------------------|
| <b>Peaks / Valleys</b> | Highlights high-volume nodes (peaks) and low-volume zones (valleys)          |
| <b>Sensitivity</b>     | Higher sensitivity filters out noise — fewer but more significant detections |

### Merge and split profiles

Right-click any profile on the chart to combine or divide periods: merge with the previous or the next profile, split a merged profile back apart, or reset to undo all merges. Use this to combine yesterday and today into one distribution or to isolate a single session out of a composite

[ SCREENSHOT PLACEHOLDER ] Right-click context menu on a profile showing the merge, split and reset options `deep-profile-merge-split-menu.png`

## Tips and common mistakes

- **"I only see one big profile / I want one per day."** VBP Period = Composite builds a single profile over everything. Switch to **Multiple** with Length Type = Days, Length Value = 1. Also note the chart's days-to-load setting caps how far back profiles can exist — increase the loaded days if older profiles are missing.
- **"The profile changes when I zoom."** Either VBP Period is **Visible** (recalculating on view is its purpose), or Automatic tick grouping is re-sizing the bars — set Manual Tick = 1 to lock levels.
- **"My profile shape differs from another platform."** Compare Input Data type, Min/Max filters, tick grouping and ETH/RTH session splitting before assuming bad data — each changes the shape legitimately.
- **Profile for one consolidation only:** VBP Period = **Custom** and select the area, or **Visible** and frame the area on screen.

- **Separate overnight and RTH profiles:** Filter Mode = **Splitted** with the RTH option (two profiles per day), or **Triple** with custom time ranges.
